- 5 AES – The Advanced Encryption Standard

- **Block Cipher** $F : \{0, 1\}^n \times \{0, 1\}^\ell \rightarrow \{0, 1\}^\ell$.
 $F_k : \{0, 1\}^\ell \rightarrow \{0, 1\}^\ell$, $F_k(x) \stackrel{\text{def}}{=} F(k, x)$.
 n is key length, ℓ is block length.
- Constructions are **heuristic**, not proofed.
- Considered as **PRP in practice**.
 - In the call for proposals for AES: *The extent to which the algorithm output is indistinguishable from a random permutation on the input block.*
- Is “**good**” if the best known attack has time complexity roughly **equivalent to a brute-force search for the key**.
 - A cipher with $n = 112$ which can be broken in time 2^{56} is insecure.
 - In a non-asymptotic setting, $2^{n/2}$ may be insecure.

The Confusion-Diffusion Paradigm

- **Goal:** Construct *concise*¹ random-looking permutations.
- **Confusion:** making the relationship between the key and the ciphertext as complex and involved as possible.
Construct a large random-looking permutation F from smaller random permutations f_i . $F_k(x) = f_1(x_1)f_2(x_2) \cdots f_i(x_i)$
- **Diffusion:** the redundancy in the statistics of the plaintext is dissipated in the statistics of the ciphertext.
- **Product cipher** combines multiple transformations.

¹A block length of n bits would require $\log(2^n!) \approx n \cdot 2^n$ bits for its representation.

A Substitution-Permutation Network

Design Principle 1 – Invertibility of The S -boxes

S -boxes must be invertible, otherwise the block cipher will not be a permutation.

Proposition 1

Let F be a keyed function defined by a SPN in which the S -boxes are all one-to-one and onto. Then regardless of the key schedule and the number of rounds, F_k is a permutation for any choice of k .

Design Principle 2 – The Avalanche Effect

- **Avalanche effect:** changing a single bit of the input affects every bit of the output.
- **Strict avalanche criterion:** a single input bit is complemented, each of the output bits changes with a 50% probability.
- **Bit independence criterion:** output bits j and k should change independently when any single input bit i is inverted, for all i, j and k .
- S -box: changing a single bit of the input changes at least two bits in the output.
- P -box: the output bits of any given S -box are spread into different S -boxes in the next round.

For 4-bit S -boxes, changing 1 bit of the input affects 2^R bits of the output after R rounds of SPN.

A Framework for KPA against Block Ciphers

KPA: know some plaintext/ciphertext pairs under the same key.

- 1 Observe relationship between PT/CT and k bits of the key.
- 2 Design a test on t bits based on the above relationship.
- 3 Search in k -bit space; a guess passes test with pr. 2^{-t} .
- 4 Use p PT/CT pairs to determine the key with exp. $2^{k-(p)t}$.

KPA against 1-Round SPN with 16-bit key

Relationship $\text{PT} \oplus \text{Key} \oplus \text{Input-of-}S\text{-boxes} = 0$.

Test on $t = 16$ bits: $\text{Input-of-}S\text{-boxes} = \text{PT} \oplus \text{Key}$.

Search in $k = 16$ bit space; passing test with pr. $1/2^{16}$.

Determine the key with $p = 1$ PT/CT pair and exp. 1.

Attacks on Reduced-Round SPNs

Attack on a 2-round SPN: 64-bit block, 128-bit key (2×64 -bit sub-keys), 16×4 -bit S -boxes, and mixing with XOR.

- Guessing 20 bits: 16 bits of the 1st sub-key, 4 bits of the 2nd.
- Guess passes the 4-bit test with pr. $1/2^4$ ($1/2^n$ for n -bit test).
- Use 8 I/O pairs to determine the key (with exp. $2^{20-4 \times 8}$).
- Break with complexity $8 \cdot 2^{20} \cdot 16 = 2^{27} \ll 2^{128}$ (16 S -boxes).

Feistel Networks

Properties of Feistel Networks

- **Idea:** Construct an invertible function from non-invertible components.
- **Round function** $f_i(R) \stackrel{\text{def}}{=} \hat{f}_i(k_i, R)$ (\hat{f}_i mangler function).
- **Output:** $L_i := R_{i-1}$ and $R_i := L_{i-1} \oplus f_i(R_{i-1})$.
- **Inverting:** $L_{i-1} := R_i \oplus f_i(R_{i-1}) = R_i \oplus f_i(L_i)$.
- **Decryption:** Operate with sub-keys in reverse order.

Proposition 2

Luby-Rackoff Theorem: Let F be a keyed function defined by a Feistel network. Then regardless of the mangler functions $\{\hat{f}_i\}$ and the number of rounds, F_k is a permutation for any choice of k .

- 5 AES – The Advanced Encryption Standard

The Design of DES

- 16-round Feistel network.
- 64-bit block
- 56-bit key, 48-bit sub-key. (64bit key with 8 check bits)
- Key schedule: 56 bits $\xrightarrow[\text{left rotation, PC}]{\text{divided into two halves}}$ 48 bits.
- Begin with Initial Permutation (IP) and end with IP^{-1} .
- Round function f is non-invertible with 32-bit I/O.
- f_i is determined by mangler function \hat{f}_i and sub-key k_i .
- S -box is a 4-to-1 function, mapping 6-bit to 4-bit.

The DES Mangler Function

An S -box in DES

An S -box

Input: $b_{0,1,\dots,5} = 011001$

Output: $S[b_{0,5}][b_{1,2,3,4}] = S[01][1100] = S[1][12] = 9 = 1001$

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15		
	+-----+																	
0		14	4	13	1	2	15	11	8	3	10	6	12	5	9	0	7	
1		0	15	7	4	14	2	13	1	10	6	12	11	9	5	3	8	
2		4	1	14	8	13	6	2	11	15	12	9	7	3	10	5	0	
3		15	12	8	2	4	9	1	7	5	11	3	14	10	0	6	13	
	+-----+																	

Key Schedule

Bits of shift is 1 or 2 in different rounds.

Weak Keys of DES

- **Weak keys:** makes the cipher behave in some undesirable way—producing *identical* sub-keys.

Weak keys (Key with check bits : key w/o check bits)

01010101	01010101	:	00000000	00000000
FEFEFEFE	FEFEFEFE	:	FFFFFFF	FFFFFFF
E0E0E0E0	F1F1F1F1	:	FFFFFFF	00000000
1F1F1F1F	0E0E0E0E	:	00000000	FFFFFFF

- **Semi-weak keys:** producing only two different sub-keys.
A pair of semi-weak keys k_1, k_2 : $F_{k_1}(F_{k_2}(M)) = M$.

Semi-weak key pairs (2 of total 6 pairs)

011F011F	010E010E	&	1F011F01	0E010E01
01E001E0	01F101F1	&	E001E001	F101F101

Chronology of DES

- 1973** NBS (NIST) publishes a call for a standard.
- 1974** DES is published in the Federal Register.
- 1977** DES is published as FIPS PUB 46.
- 1990** Differential cryptanalysis with CPA of 2^{47} plaintexts.
- 1997** DESCHALL Project breaks DES in public.
- 1998** EFF's Deep Crack breaks DES in 56hr at \$250,000.
- 1999** Triple DES.
- 2001** AES is published in FIPS PUB 197.
- 2004** FIPS PUB 46-3 is withdrawn.
- 2006** COPACOBANA breaks DES in 9 days at \$10,000.
- 2008** RIVYERA breaks DES within one day.

Double Encryption

- **Internal tampering vs. Black-box constructions:** by modifying DES – in even the smallest way – we lose the confidence we have gained in DES.
- **Double encryption:** $y = F'_{k_1, k_2}(x) \stackrel{\text{def}}{=} F_{k_2}(F_{k_1}(x))$.

The Meet-In-the-Middle Attack

- $z_0 = F_{k_1}(x) = F_{k_2}^{-1}(y) \iff y = F'_{k_1, k_2}(x)$.
- Key pair (k_1, k_2) satisfies the equation with probability 2^{-n} .
- The number of such key pairs is $2^{2n}/2^n = 2^n$.
- With another two I/O pairs, the expected number of key pairs is $2^n/2^{2n} = 2^{-n}$. So that is it!
- $\mathcal{O}(2^n)$ time and $\mathcal{O}(2^n)$ space.

Triple Encryption

- $k_1 = k_2 = k_3$: a single F with backward compatibility.
- $k_1 \neq k_2 \neq k_3$: time 2^{2n} under the meet-in-the-middle attack.
- $k_1 = k_3 \neq k_2$: time 2^{2n} with 1 I/O pair; time 2^n with 2^n pair.
- **Triple-DES** (3DES): strong, but small block length and slow.

- 3 DES – The Data Encryption Standard
- 4 Increasing the Key Length of a Block Cipher
- 5 AES – The Advanced Encryption Standard**

AES – The Advanced Encryption Standard

- In 1997, NIST calls for AES.
- In 2001, Rijndael [J. Daemen & V. Rijmen] becomes AES.
- The first publicly accessible cipher for top secret information.
- Not only security, also efficiency and flexibility, etc.
- 128-bit block length and 128-, 192-, or 256-bit keys.
- Not a Feistel structure, but a SPN.
- Only non-trivial attacks are for reduced-round variants.
 - 2^{27} on 6-round of 10-round for 128-bit keys.
 - 2^{188} on 8-round of 12-round for 192-bit keys.
 - 2^{204} on 8-round of 14-round for 256-bit keys.

The AES Construction

State: 4-by-4 array of bytes. The initial state is the plaintext.

- 1 AddRoundKey:** state XORed with the 128-bit sub-key.
- 2 SubBytes:** each byte replaced according to a single S -box.
- 3 ShiftRows:** each row cyclically shifted.
- 4 MixColumns:** each column multiplied by a matrix.

See an animation of Rijndael!.

- Block cipher is PRP.
- confusion & diffusion, SPN, Feistel network, avalanche effect.
- DES, 3DES, AES.
- reduced round, meet-in-the-middle, differential and linear cryptanalysis.
